What Are Graph Neural Networks?

- GNNs are a type of deep learning model designed for graph-structured data
- Graphs consist of:
 - Nodes (Vertices): Represent entities (e.g., people in a social network).
 - Edges/Links: Represent relationships or interactions (e.g., friendships).

- GNNs leverage the structure of graphs to learn meaningful representations.

Message Passing:

Nodes aggregate information from neighbors.

Node Embeddings

Transform features into a low-dimensional vector space.

Graph Aggregation:

Pool node embeddings to form a graph-level representation.

- Graph data is everywhere in real-world applications.
- Traditional neural networks struggle with non-Euclidean data.
- GNNs enable learning directly on graph structures, capturing both:
 - Node features.
 - Topological relationships (connectivity).

Examples of Graph Data

- Social networks: Users as nodes, friendships as edges.
- Molecular graphs: Atoms as nodes, chemical bonds as edges.
- Knowledge graphs: Entities as nodes, relationships as edges.
- Transportation networks: Locations as nodes, roads as edges.
